SOLID XAU/USD SCAN AND ALERT RICHSCHEME 001

What works today, what the evidence says, and what to do next.

Signals work. Signal confidence is not yet proven.

54.5%
resolved-only hit rate
66 TP1 / 121 resolved

+0.64R
mean on resolved sample
Replay-reported average

37
automated tests passing
Engineering, not strategy proof

What is already usable

- Live XAU/USD analysis from BiQuote on H4, H1 and M15.
- BUY/SELL LIMIT, BUY/SELL STOP and MARKET/IMMEDIATE scenarios.
- Entry, SL, TP1/TP2, risk/reward, conditions and confluence grade.
- Local logging and candle archive; optional Telegram and dashboard.
- OANDA history replay and broker-CSV import for research.

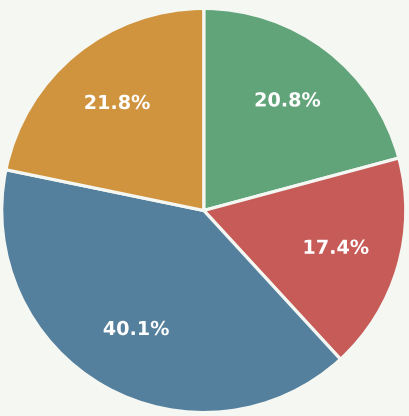

What a signal does not mean

The scanner does not place or manage trades. A grade is a strategy confluence score, not a calibrated probability of winning. In data-only mode there is no connected account balance; risk checks use a $10,000 fallback baseline. Do not treat that baseline as your account risk.

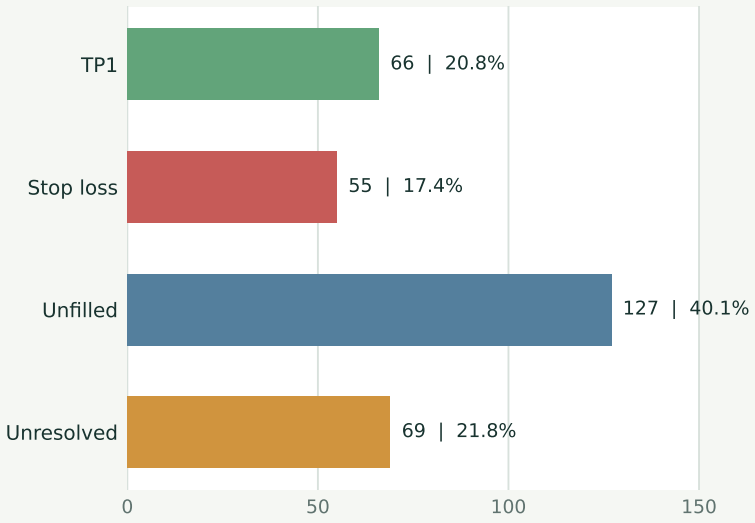

Replay snapshot | OANDA practice | 23–29 Sep 2026

317 signals across 418 M15 decisions; counts include unfilled and unresolved setups.

Share of all generated signals

Outcome counts (n = 317)

Resolved-only hit rate = 66 / (66 + 55) = 54.5%. This is not a 54.5% probability for a new signal.

One short sample; candle-based estimates omit spread, slippage, fees and overlapping-position constraints.

Use it now. Validate it next.

The project has a working signal pipeline; the next milestone is trustworthy evidence.

What you can do with it today

1 Scan live `python main.py`

Polls BiQuote; prints/logs candidate setups and archives fetched candles.

2 Open the dashboard `streamlit run dashboard/app.py`

Review saved setups and signal types locally.

3 Replay archived history `python -m scanner.signal_replay --source OANDA-PRACTICE --symbol XAU_USD`

Evaluate signals against later M15 candles; add --from / --to to bound dates.

4 Bring your broker data `python -m scanner.import_market_csv <file> --symbol XAUUSD --timeframe H1 --source <broker>`

Keep broker candles separate; specify --timezone for timezone-naive exports.

Confidence: early and uncalibrated

The replay shows a 54.5% hit rate among 121 resolved outcomes, not among all signals. 127/317 were unfilled; 69/317 remained unresolved. Grades have not been mapped to probabilities, and one week cannot establish performance across market regimes.

Where we are heading

01 Match the feed

Build a longer archive from the broker/feed you actually trade; XAU/USD prices differ.

02 Test realistic fills

Replay multiple market regimes with spread, slippage, fees and position constraints.

03 Calibrate grades

Report expectancy and outcomes by grade, signal type and held-out time periods.

Critical operating caveats

- BiQuote is a rolling live feed; OANDA practice replay is a different price feed.
- The scanner never executes trades. Verify levels and risk at your own broker.
- Data-only risk checks use a $10,000 fallback balance, not your live equity.
- Backtest outcomes are OHLC estimates, not a broker execution simulation.

Bottom line: usable for observing and researching candidate setups today; not yet proven as a profitable strategy.
